## Data Sheet

## FEATURES

## 4 A peak output current

## Working voltage

High-side or low-side relative to input: 565 V peak
High-side to low-side differential: 800 V peak
High frequency operation: 1 MHz maximum
3.3 V to 5 V CMOS input logic
4.5 V to 18 V output drive

UVLO at $2.5 \mathrm{~V}_{\mathrm{DD} 1}$
ADuM3223A/ADuM4223A UVLO at 4.1 V VD2
ADuM3223B/ADuM4223B UVLO at $7.0 \mathrm{~V} \mathrm{~V}_{\mathrm{DD} 2}$
ADuM3223C/ADuM4223C UVLO at 11.0 V VD 2

## Precise timing characteristics

49 ns maximum isolator and driver propagation delay
5 ns maximum channel-to-channel matching

## CMOS input logic levels

High common-mode transient immunity: $>50 \mathrm{kV} / \mu \mathrm{s}$
Enhanced system-level ESD performance per IEC 61000-4-x
High junction temperature operation: $125^{\circ} \mathrm{C}$
Default low output
Safety and regulatory approvals
ADuM3223 narrow body, 16-lead SOIC
UL 15773000 V rms input-to-output withstand voltage ADuM4223 wide body, 16-lead SOIC

UL 15775000 V rms input-to-output withstand voltage
Qualified for automotive applications

## APPLICATIONS

Switching power supplies Isolated IGBT/MOSFET gate drives Industrial inverters

## GENERAL DESCRIPTION

The ADuM3223/ADuM4223 ${ }^{1}$ are 4 A isolated, half-bridge gate drivers that employ the Analog Devices, Inc., $i$ Coupler ${ }^{\bullet}$ technology to provide independent and isolated high-side and low-side outputs. The ADuM3223 provides 3000 V rms isolation in the narrow body, 16-lead SOIC package, and the ADuM4223 provides 5000 V rms isolation in the wide body, 16-lead SOIC package. Combining high speed CMOS and monolithic transformer technology, these isolation components provide outstanding performance characteristics superior to the alternatives, such as the combination of pulse transformers and gate drivers.
The ADuM3223/ADuM4223 isolators each provide two independent isolated channels. They operate with an input supply ranging from 3.0 V to 5.5 V , providing compatibility with lower voltage systems. In comparison to gate drivers employing high voltage level translation methodologies, the ADuM3223/ADuM4223 offer the benefit of true, galvanic isolation between the input and each output. Each output may be continuously operated up to 560 V peak relative to the input, thereby supporting low-side switching to negative voltages. The differential voltage between the high-side and low-side may be as high as 800 V peak.
As a result, the ADuM3223/ADuM4223 provide reliable control over the switching characteristics of IGBT/MOSFET configurations over a wide range of positive or negative switching voltages.

${ }^{1}$ Protected by U.S. Patents 5,952,849; 6,873,065; 7,075,239. Other patents pending.

## SPECIFICATIONS

## ELECTRICAL CHARACTERISTICS—5 V OPERATION

All voltages are relative to their respective ground. $4.5 \mathrm{~V} \leq \mathrm{V}_{\mathrm{DD} 1} \leq 5.5 \mathrm{~V}, 4.5 \mathrm{~V} \leq \mathrm{V}_{\mathrm{DD} 2} \leq 18 \mathrm{~V}$, unless stated otherwise. All minimum/ maximum specifications apply over $\mathrm{T}_{\mathrm{J}}=-40^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$. All typical specifications are at $\mathrm{T}_{\mathrm{J}}=25^{\circ} \mathrm{C}, \mathrm{V}_{\mathrm{DD} 1}=5 \mathrm{~V}, \mathrm{~V}_{\mathrm{DD} 2}=12 \mathrm{~V}$. Switching specifications are tested with CMOS signal levels.

| Refresh Rate | $\mathrm{fr}_{\mathrm{r}}$ |  | 1.1 |  | Mbps |  |

${ }^{1}$ Short-circuit duration less than $1 \mu \mathrm{~s}$. Average power must conform to the limit shown under the Absolute Maximum Ratings.
${ }^{2}$ The minimum pulse width is the shortest pulse width at which the specified timing parameter is guaranteed.
${ }^{3}$ The maximum data rate is the fastest data rate at which the specified timing parameter is guaranteed.
${ }^{4}$ toLH propagation delay is measured from the time of the input rising logic high threshold, $\mathrm{V}_{\mathbb{H}}$, to the output rising $10 \%$ level of the $\mathrm{V}_{\text {ox }}$ signal. tohe propagation delay is measured from the input falling logic low threshold, $\mathrm{V}_{\mathrm{L}}$, to the output falling $90 \%$ threshold of the $\mathrm{V}_{0 \times}$ signal. See Figure 20 for waveforms of propagation delay parameters.
${ }^{5}$ tpsk is the magnitude of the worst-case difference in $\mathrm{t}_{\mathrm{DLH}}$ and/or $\mathrm{t}_{\mathrm{DHL}}$ that is measured between units at the same operating temperature, supply voltages, and output load within the recommended operating conditions. See Figure 20 for waveforms of propagation delay parameters.
${ }^{6}$ Channel-to-channel matching is the absolute value of the difference in propagation delays between the two channels.

| Output Voltage ${ }^{1}$ | VoA | -0.5 V to $\mathrm{V}_{\text {DDA }}+0.5 \mathrm{~V}$ |
|  | Vов | -0.5 V to $\mathrm{V}_{\text {DDB }}+0.5 \mathrm{~V}$ |
| Average Output Current, per Pin ${ }^{2}$ | lo | -35 mA to +35 mA |
| Common-Mode Transients ${ }^{3}$ | CM H CM Cl | $-100 \mathrm{kV} / \mu \mathrm{s}$ to $+100 \mathrm{kV} / \mu \mathrm{s}$ |

${ }^{1}$ All voltages are relative to their respective ground.
${ }^{2}$ See Figure 2 and Figure 3 for information on maximum allowable current for various temperatures.
${ }^{3}$ Refers to common-mode transients across the insulation barrier. Commonmode transients exceeding the absolute maximum rating can cause latch-up or permanent damage.

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ESD CAUTION

|  | ESD (electrostatic discharge) sensitive device. <br> Charged devices and circuit boards can discharge <br> without detection. Although this product features <br> patented or proprietary protection circuitry, damage <br> may occur on devices subjected to high energy ESD. <br> Therefore, proper ESD precautions should be taken to <br> avoid performance degradation or loss of functionality. |

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

NOTES

1. $\mathrm{NC}=$ NO CONNECT.
2. NC = NO CONNECT TO THIS PIN.

Figure 4. Pin Configuration

Table 14. ADuM3223/ADuM4223 Pin Function Descriptions

| Pin No. ${ }^{1}$ | Mnemonic | Description |
| :---: | :---: | :---: |
| 1 | $V_{\text {IA }}$ | Logic Input A. |
| 6, 7, 12, 13 | NC | No Connect. |
| 2 | $V_{\text {IB }}$ | Logic Input B. |
| 3, 8 | VDD1 | Input Supply Voltage. |
| 4 | $\mathrm{GND}_{1}$ | Ground Reference for Input Logic Signals. |
| 5 | DISABLE | Input Disable. Disables the isolator inputs and refresh circuits. Outputs take on default low state within $3 \mu \mathrm{~s}$ of DISABLE $=H$ assertion. Outputs return to the input state within $1 \mu$ of DISABLE $=L$ assertion. |
| 9 | $\mathrm{GND}_{\text {B }}$ | Ground Reference for Output B. |
| 10 | $\mathrm{V}_{\text {OB }}$ | Output B. |
| 11 | $V_{\text {dDB }}$ | Output B Supply Voltage. |
| 14 | $\mathrm{GND}_{\text {A }}$ | Ground Reference for Output A. |
| 15 | $V_{\text {OA }}$ | Output A. |
| 16 | V DDA | Output A Supply Voltage. |

${ }^{1}$ Pin 3 and Pin 8 are internally connected; connecting both pins to supply $V_{D D 1}$ is recommended.

For specific layout guidelines, refer to the AN-1109 Application Note, Recommendations for Control of Radiated Emissions with iCoupler Devices.

## APPLICATIONS INFORMATION

## PC BOARD LAYOUT

The ADuM3223/ADuM4223 digital isolators require no external interface circuitry for the logic interfaces. Power supply bypassing is required at the input and output supply pins, as shown in Figure 19. Use a small ceramic capacitor with a value between $0.01 \mu \mathrm{~F}$ and $0.1 \mu \mathrm{~F}$ to provide a good high frequency bypass. On the output power supply pin, $\mathrm{V}_{\mathrm{DDA}}$ or $\mathrm{V}_{\mathrm{DDB}}$, it is recommended to also add a $10 \mu \mathrm{~F}$ capacitor to provide the charge required to drive the gate capacitance at the ADuM3223/ ADuM4223 outputs. On the output supply pin, the bypass capacitor use of vias should be avoided or multiple vias should be employed to reduce the inductance in the bypassing. The total lead length between both ends of the smaller capacitor and the input or output power supply pin should not exceed 5 mm .

Figure 19. Recommended PCB Layout

## PROPAGATION DELAY-RELATED PARAMETERS

Propagation delay is a parameter that describes the time it takes a logic signal to propagate through a component. The propagation delay to a logic low output can differ from the propagation delay to a logic high output. The ADuM3223/ADuM4223 specify $t_{\text {DLH }}$ (see Figure 20) as the time between the rising input high logic threshold, $\mathrm{V}_{\mathrm{IH}}$, to the output rising $10 \%$ threshold. Likewise, the falling propagation delay, $t_{\text {DHL }}$, is defined as the time between the input falling logic low threshold, $\mathrm{V}_{\text {IL }}$, and the output falling $90 \%$ threshold. The rise and fall times are dependent on the loading conditions and are not included in the propagation delay, which is the industry standard for gate drivers.

Figure 20. Propagation Delay Parameters
Channel-to-channel matching refers to the maximum amount that the propagation delay differs between channels within a single ADuM3223/ADuM4223 component.

In Figure 5, the ADuM3223/ADuM4223 output waveforms for a 12 V output are shown for a $\mathrm{C}_{\mathrm{GS}}$ of 2 nF . Note the small amount of ringing of the output in Figure 5 with $\mathrm{C}_{\mathrm{GS}}$ of 2 nF , $\mathrm{R}_{\text {SW }}$ of $1.1 \Omega, \mathrm{R}_{\mathrm{GATE}}$ of $0 \Omega$, and a calculated Q factor of 0.75 , where less than 1 is desired for good damping.
Output ringing can be reduced by adding a series gate resistance to dampen the response. For applications of less than 1 nF load, it is recommended to add a series gate resistor of about $2 \Omega$ to $5 \Omega$.

## BOOT-STRAPPED HALF-BRIDGE OPERATION

The ADuM3223/ADuM4223 are well suited to the operation of two output gate signals that are referenced to separate grounds, as in the case of a half-bridge configuration. Because isolated auxiliary supplies are often expensive, it is beneficial to reduce the amount of supplies. One method to perform this is to use a boot-strap configuration for the high-side supply of the ADuM3223/ADuM4223. In this topology, the decoupling capacitor, $\mathrm{C}_{\mathrm{A}}$, acts as the energy storage for the high-side supply, and is filled whenever the low-side switch is closed, bringing $\mathrm{GND}_{\mathrm{A}}$ to $\mathrm{GND}_{\mathrm{B}}$. During the charging time of $\mathrm{C}_{\mathrm{A}}$, the dv/dt of the $V_{\text {DDA }}$ voltage must be controlled to reduce the possibility of glitches on the output. Keeping the dv/dt below $0.5 \mathrm{~V} / \mu \mathrm{s}$ is recommended for the ADuM3223/ADuM4223. This can be controlled by introducing a series resistance, $\mathrm{R}_{\text {воот, }}$ into the charging path of $\mathrm{C}_{\mathrm{A}}$. As an example, if $\mathrm{V}_{\mathrm{AUX}}$ is $12 \mathrm{~V}, \mathrm{C}_{\mathrm{A}}$ has a total capacitance of $10 \mu \mathrm{~F}$, and the forward voltage drop of the bootstrap diode is 1 V :

$$
R_{\text {BOOT }}=\frac{V_{A U X}-V_{D_{B O O T}}}{C_{A} \times d v / d t_{\max }}=\frac{12 \mathrm{~V}-1 \mathrm{~V}}{10 \mu \mathrm{~F} \times 0.5 \mathrm{~V} / \mu \mathrm{s}}=2.2 \Omega
$$

## DC CORRECTNESS AND MAGNETIC FIELD IMMUNITY

Positive and negative logic transitions at the isolator input cause narrow ( $\sim 1 \mathrm{~ns}$ ) pulses to be sent to the decoder via the transformer. The decoder is bistable and is, therefore, either set or reset by the pulses, indicating input logic transitions. In the absence of logic transitions of more than $1 \mu \mathrm{~s}$ at the input, a periodic set of refresh pulses indicative of the correct input state are sent to ensure dc correctness at the output.
If the decoder receives no internal pulses for more than about $3 \mu \mathrm{~s}$, the input side is assumed to be unpowered or nonfunctional, in which case, the isolator output is forced to a default low state by the watchdog timer circuit. In addition, the outputs are in a low default state while the power is coming up before the UVLO threshold is crossed.

The ADuM3223/ADuM4223 is immune to external magnetic fields. The limitation on the ADuM3223/ADuM4223 magnetic field immunity is set by the condition in which induced voltage in the transformer receiving coil is sufficiently large to either falsely set or reset the decoder. The following analysis defines the conditions under which this can occur. The 3 V operating condition of the ADuM3223/ADuM4223 is examined because it represents the most susceptible mode of operation. The pulses at the transformer output have an amplitude greater than 1.0 V . The decoder has a sensing threshold at about 0.5 V , therefore establishing a 0.5 V margin in which induced voltages can be tolerated. The voltage induced across the receiving coil is given by

$$
V=(-d \beta / d t) \sum \pi r_{n}^{2}, n=1,2, \ldots, N
$$

where:
$\beta$ is the magnetic flux density (gauss).
$N$ is the number of turns in the receiving coil.
$r_{n}$ is the radius of the nth turn in the receiving coil ( cm ).

Given the geometry of the receiving coil in the ADuM3223/ ADuM4223 and an imposed requirement that the induced voltage is, at most, $50 \%$ of the 0.5 V margin at the decoder, a maximum allowable magnetic field is calculated, as shown in Figure 23.

Figure 23. Maximum Allowable External Magnetic Flux Density
For example, at a magnetic field frequency of 1 MHz , the maximum allowable magnetic field of 0.08 kgauss induces a voltage of 0.25 V at the receiving coil. This is about $50 \%$ of the sensing threshold and does not cause a faulty output transition. Similarly, if such an event were to occur during a transmitted pulse (and had the worst-case polarity), the received pulse is reduced from $>1.0 \mathrm{~V}$ to 0.75 V , still well above the 0.5 V sensing threshold of the decoder.

The preceding magnetic flux density values correspond to specific current magnitudes at given distances away from the ADuM3223/ADuM4223 transformers. Figure 24 expresses these allowable current magnitudes as a function of frequency for selected distances. As shown, the ADuM3223/ADuM4223 are immune and only can be affected by extremely large currents operated at a high frequency and very close to the component. For the 1 MHz example, a 0.2 kA current must be placed 5 mm away from the ADuM3223/ADuM4223 to affect the component's operation.

Figure 24. Maximum Allowable Current for Various Current-to-ADuM3223/ADuM4223 Spacings

## POWER CONSUMPTION

The supply current at a given channel of the ADuM3223/ ADuM4223 isolator is a function of the supply voltage, channel data rate, and channel output load.

For each input channel, the supply current is given by

$$
\begin{array}{ll}
I D D I=I D D I(Q) & f \leq 0.5 f r \\
I D D I=I D D I(D) \times(2 f-f r)+I D D I(Q) & f>0.5 f r
\end{array}
$$

For each output channel, the supply current is given by

$$
\begin{aligned}
& I D D O=I D D O(Q) \quad f \leq 0.5 f r \\
& I D D O=(I D D O(D)+(0.5) \times C L V D D O) \times(2 f-f r)+ \\
& I D D O(Q)
\end{aligned}
$$

$$
f>0.5 f r
$$

where:
$I D D I(D), I D D O(D)$ are the input and output dynamic supply currents per channel (mA/Mbps).
$C L$ is the output load capacitance ( pF ).
$V D D O$ is the output supply voltage ( V ).
$f$ is the input logic signal frequency $(\mathrm{MHz}$, half of the input data rate, NRZ signaling).
$f r$ is the input stage refresh rate (Mbps).
$\operatorname{IDDI}(Q), I D D O(Q)$ are the specified input and output quiescent supply currents (mA).
To calculate the total supply current, the supply currents for each input and output channel corresponding to IDD1, IDDA, and IDDB are calculated and totaled.

Figure 9 provides total input IDD1 supply current as a function of data rate for both input channels. Figure 10 provides total IDDA or IDDB supply current as a function of data rate for both outputs loaded with 2 nF capacitance.

## INSULATION LIFETIME

All insulation structures eventually break down when subjected to voltage stress over a sufficiently long period. The rate of insulation degradation is dependent on the characteristics of the voltage waveform applied across the insulation. In addition to the testing performed by the regulatory agencies, Analog Devices carries out an extensive set of evaluations to determine the lifetime of the insulation structure within the ADuM3223/ ADuM4223.
Analog Devices performs accelerated life testing using voltage levels higher than the rated continuous working voltage. Acceleration factors for several operating conditions are determined. These factors allow calculation of the time to failure at the actual working voltage.
The values shown in Table 11 summarize the peak voltage for 50 years of service life for a bipolar ac operating condition, and the maximum CSA/VDE approved working voltages. In many cases, the approved working voltage is higher than 50-year service life voltage. Operation at these high working voltages can lead to shortened insulation life in some cases.
The insulation lifetime of the ADuM3223/ADuM4223 depends on the voltage waveform type imposed across the isolation barrier. The iCoupler insulation structure degrades at different rates depending on whether the waveform is bipolar ac, unipolar ac, or dc. Figure 25, Figure 26, and Figure 27 illustrate these different isolation voltage waveforms.
A bipolar ac voltage environment is the worst case for the $i$ Coupler products and is the 50 -year operating lifetime that Analog Devices recommends for maximum working voltage. In the case of unipolar ac or dc voltage, the stress on the insulation
is significantly lower. This allows operation at higher working voltages while still achieving a 50 -year service life. Any crossinsulation voltage waveform that does not conform to Figure 26 or Figure 27 should be treated as a bipolar ac waveform, and its peak voltage should be limited to the 50 -year lifetime voltage value listed in Table 12.

Note that the voltage presented in Figure 26 is shown as sinusoidal for illustration purposes only. It is meant to represent any voltage waveform varying between 0 V and some limiting value. The limiting value can be positive or negative, but the voltage cannot cross 0 V .

${ }^{1} \mathrm{Z}=$ RoHS Compliant Part.
${ }^{2}$ ADuM3223W = Qualified for Automotive Applications.

## AUTOMOTIVE PRODUCTS

The ADuM3223W models are available with controlled manufacturing to support the quality and reliability requirements of automotive applications. Note that these automotive models may have specifications that differ from the commercial models; therefore, designers should review the Specifications section of this data sheet carefully. Only the automotive grade products shown are available for use in automotive applications. Contact your local Analog Devices account representative for specific product ordering information and to obtain the specific Automotive Reliability reports for these models.

[^0]:    ${ }^{1}$ Short-circuit duration less than $1 \mu \mathrm{~s}$. Average power must conform to the limit shown under the Absolute Maximum Ratings.
    ${ }^{2}$ The minimum pulse width is the shortest pulse width at which the specified timing parameter is guaranteed.
    ${ }^{3}$ The maximum data rate is the fastest data rate at which the specified timing parameter is guaranteed.
    ${ }^{4}$ toL propagation delay is measured from the time of the input rising logic high threshold, $\mathrm{V}_{\mathbb{H}}$, to the output rising $10 \%$ level of the $\mathrm{V}_{\text {ox }}$ signal. toh propagation delay is measured from the input falling logic low threshold, $\mathrm{V}_{\mathrm{IL}}$, to the output falling $90 \%$ threshold of the $\mathrm{V}_{\text {Ox }}$ signal. See Figure 20 for waveforms of propagation delay parameters.
    ${ }^{5} \mathrm{t}_{\mathrm{PSK}}$ is the magnitude of the worst-case difference in $\mathrm{t}_{\mathrm{DLH}}$ and/or $\mathrm{t}_{\mathrm{DHL}}$ that is measured between units at the same operating temperature, supply voltages, and output load within the recommended operating conditions. See Figure 20 for waveforms of propagation delay parameters.
    ${ }^{6}$ Channel-to-channel matching is the absolute value of the difference in propagation delays between the two channels.
